Quality feed for white Gold

Subsoiling about 25 cm deep, 10kg/ha grassed and exhaust gas+HC placed into the soil behind the tines.

Heavy rainfall after subsoiling led the water to deeper sections the top of soil could warm up quicker.

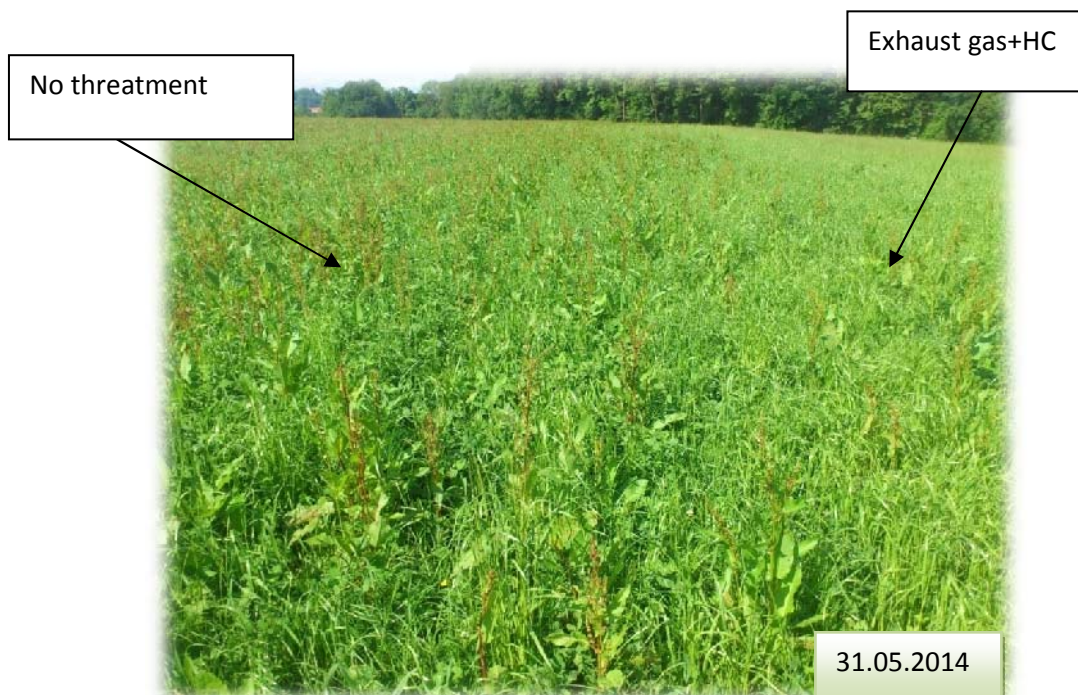

After the first cut it was already clear to see, that soil organism are developing quicker by warmed up. Higher efficiency of phosphate and microelements, gave the grass a very quick development.

One week later the valuable grass was developing quicker. Weed was pressed down.

Significant to see was that grass and clover have grown up very voluminous, but weed has been reduced.

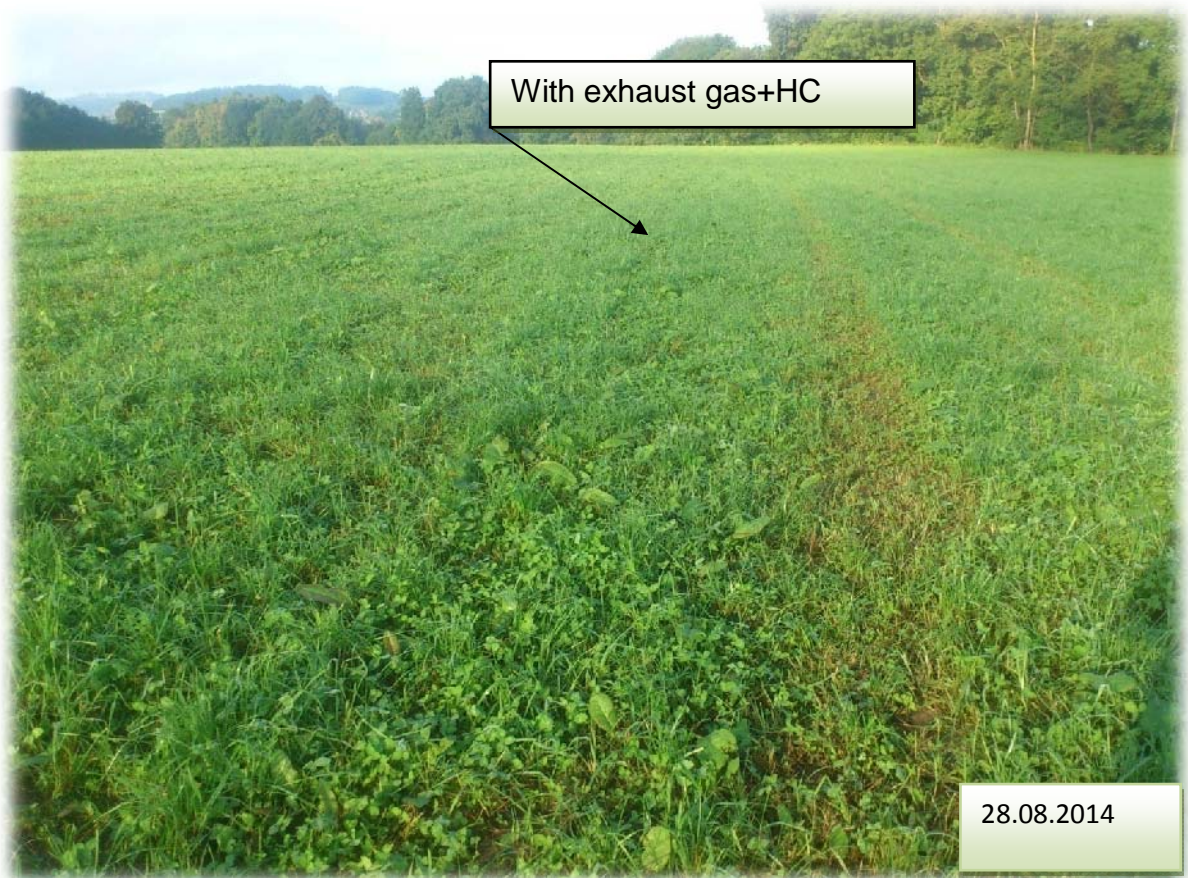

With exhaust gas+HC

This is top quality feed

At that date was realized a height of white clover up to 50 cm

Again quickly growing up of quality grass.
